

Am9101/Am91L01/Am2101 FAMILY

256x4 Static R/W Random Access Memories

2

PART NUMBER	Am2101	Am2101-2	Am9101A Am91L01A Am2101-1	Am9101B Am91L01B	Am9101C Am91L01C	Am9101D
ACCESS TIME	1000ns	650ns	500ns	400ns	300ns	250ns

DISTINCTIVE CHARACTERISTICS

- 256 x 4 organization
- Low operating power
125mW Typ; 290mW maximum — standard power
100mW Typ; 175mW maximum — low power
- DC standby mode reduces power up to 84%
- Logic voltage levels identical to TTL
- High output drive — two full TTL loads
- High noise immunity — full 400mV
- Single 5 volt power supply —
tolerances: ±5% commercial, ±10% military
- Uniform switching characteristics — access times insensitive to supply variations, addressing patterns and data patterns
- Both military and commercial temperature ranges available
- Two chip enable inputs
- Output disable control
- Zero address set-up and hold times for simplified timing
- 100% MIL-STD-883 reliability assurance testing

FUNCTIONAL DESCRIPTION

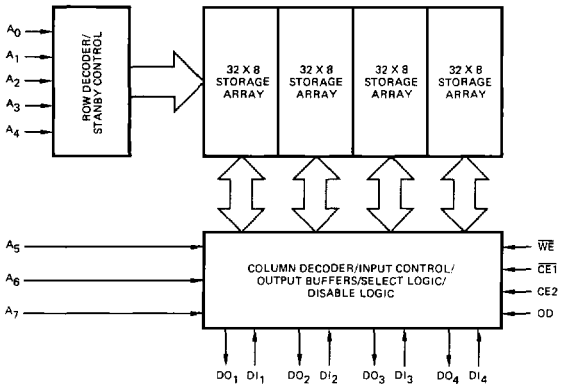

The Am9101/Am91L01 series of devices are high-performance, low-power, 1024-bit, static, read/write random access memories. They offer a wide range of access times including versions as fast as 200ns. Each memory is implemented as 256 words by 4 bits per word. This organization permits efficient design of small memory systems and allows finer resolution of incremental memory depth.

These memories may be operated in a DC standby mode for reductions of as much as 84 percent of the normal power dissipation. Data can be retained with a power supply as low as 1.5 volts. The low power Am91L01 series offer reduced power dissipation during normal operating conditions and even lower dissipation in the standby mode.

The Chip Enable input control signals act as high order address lines and they control the write amplifier and the output buffers. The Output Disable signal provides independent control over the output state of enabled chips.

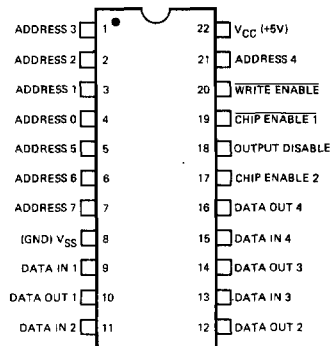

These devices are all fully static and no refresh operations or sense amplifiers or clocks are required. Input and output signal levels are identical to TTL specifications, providing simplified interfacing and high noise immunity. The outputs will drive two full TTL loads for increased fan-out and better bus interfacing capability.

MOS-346

DEFINITION OF TERMS

FUNCTIONAL TERMS

$\overline{CE1}$, $CE2$ Chip Enable Signals. Read and Write cycles can be executed only when both $\overline{CE1}$ is low and $CE2$ is high.

\overline{WE} Active LOW Write Enable. Data is written into the memory if \overline{WE} is LOW and read from the memory if \overline{WE} is HIGH.

Static RAM A random access memory in which data is stored in bistable latch circuits. A static memory will store data as long as power is supplied to the chip without requiring any special clocking or refreshing operations.

N-Channel An insulated gate field effect transistor technology in which the transistor source and drain are made of N-type material, and electrons serve as the carriers between the two regions. N-Channel transistors exhibit lower thresholds and faster switching speeds than P-Channel transistors.

SWITCHING TERMS

t_{OD} Output enable time. Delay time from falling edge of OD to output on.

t_{RC} Read Cycle Time. The minimum time required between successive address changes while reading.

t_A Access Time. The time delay between application of an address and stable data on the output when the chip is enabled.

t_{CO} Access Time from Chip Enable. The minimum time during which the chip enable must be LOW prior to reading data on the output.

t_{OH} Minimum time which will elapse between change of address and any change of the data output.

t_{DF1} Time delay between output disable HIGH and output data float.

t_{DF2} Time delay between chip enable OFF and output data float.

t_{WC} Write Cycle Time. The minimum time required between successive address changes while writing.

t_{AW} Address Set-up Time. The minimum time prior to the falling edge of the write enable during which the address inputs must be correct and stable.

t_{WP} The minimum duration of a LOW level on the write enable guaranteed to write data.

t_{WR} Address Hold Time. The minimum time after the rising edge of the write enable during which the address must remain steady.

t_{DW} Data Set-up Time. The minimum time that the data input must be steady prior to the rising edge of the write enable.

t_{DH} Data Hold Time. The minimum time that the data input must remain steady after the rising edge of the write enable.

t_{CW} Chip Enable Time during Write. The minimum duration of a LOW level on the Chip Select prior to the rising edge of \overline{WE} to guarantee writing.

POWER DOWN STANDBY OPERATION

The Am9101/Am91L01 Family is designed to maintain storage in a standby mode. The standby mode is entered by lowering V_{CC} to around 1.5–2.0 volts (see table and graph below). When the voltage to the device is reduced, the storage cells are isolated from the data lines, so their contents will not change. The standby mode may be used by a battery operated backup power supply system, or, in a

large system, memory pages not being accessed can be placed in standby to save power. A standby recovery time must elapse following restoration of normal power before the memory may be accessed.

To ensure that the output of the device is in a high impedance OFF state during standby, the chip select should be held at V_{IH} or V_{CES} during the entire standby cycle.

STANDBY OPERATING CONDITIONS OVER TEMPERATURE RANGE

Parameters	Description	Test Conditions	Min.	Typ.	Max.	Units	
V_{PD}	V_{CC} in Standby Mode		1.5				
I_{PD}	I_{CC} in Standby Mode	$T_A = 0^\circ\text{C}$ All Inputs = V_{PD}	$V_{PD} = 1.5\text{V}$	Am91L01	11	25	mA
